<b>2</b>	Modular Forms on $\Gamma(1)$	5

## 1 Introduction

06 Oct 2022, Lecture 1

**Definition 1.1.** We define the following groups:

$$\mathfrak{H} = \{ \tau \in \mathbb{C} \mid \text{Im}(\tau) > 0 \}$$

$$GL_2(\mathbb{R})^+ = \{ g \in GL_2(\mathbb{R}) \mid \det(g) > 0 \}$$

$$\Gamma(1) = SL_2(\mathbb{Z}) = \{ g \in M_2(\mathbb{Z}) \mid \det(g) = 1 \}.$$

Note that  $\Gamma(1)$  is a subgroup of  $GL_2(\mathbb{R})^+$ .

**Lemma 1.1.**  $GL_2(\mathbb{R})^+$  acts transitively on  $\mathfrak{H}$  by Möbius transformations.

*Proof.* Let 
$$g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(\mathbb{R})^+, \tau \in \mathfrak{H}$$
. Then

$$\operatorname{Im}(g\tau) = \frac{1}{2i} \left( \frac{a\tau + b}{c\tau + d} - \frac{a\overline{\tau} + b}{c\overline{\tau} + d} \right) = \frac{1}{2i} \frac{(ad - bc)(\tau - \overline{\tau})}{|c\tau + d|^2} = \frac{\det(g)\operatorname{Im}(\tau)}{|c\tau + d|^2} > 0,$$

so  $g\tau \in \mathfrak{H}$ . This action is transitive since

$$x + iy \in \mathfrak{H} \implies \begin{pmatrix} y & x \\ 0 & 1 \end{pmatrix} i = x + iy,$$

so everything in  $\mathfrak{H}$  is conjugate to i.

**Definition 1.2.** If  $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(\mathbb{R})^+$  and  $\tau \in \mathfrak{H}$ , then define

$$j(q,\tau) = c\tau + d.$$

This is called a **modular cocycle**. If  $k \in \mathbb{Z}$  and  $f : \mathfrak{H} \to \mathbb{C}$ , then

$$f|_k[g]:\mathfrak{H} o\mathbb{C}$$

is defined by

$$f|_{k}[g](\tau) = \det(g)^{k-1} f(g\tau) j(g,\tau)^{-k}.$$

This is the weight k action of g on f.

**Lemma 1.2.** This is a right action of  $GL_2(\mathbb{R})^+$ : if  $g, h \in GL_2(\mathbb{R})^+$ , then

$$f|_{k}[gh] = (f|_{k}[g])|_{k}[h].$$

*Proof.* We compute

$$(f|_{k}[g])|_{k}[h](\tau) = \det(h)^{k-1}f|_{k}[g](h\tau)j(h,\tau)^{-k} = \det(h)^{k-1}\det(g)^{k-1}f(gh\tau)j(g,h\tau)^{-k}j(h,\tau)^{-k} \stackrel{?}{=} \det(gh)^{k-1}f(gh\tau)j(gh,\tau)^{-k} = f|_{k}[gh](\tau).$$

Hence we need to check that  $j(gh,\tau)=j(gh,\tau)j(h,\tau)$ . Note that if  $g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ , then

$$g\begin{pmatrix} \tau & 1 \end{pmatrix} = \begin{pmatrix} a\tau + b \\ c\tau + d \end{pmatrix} = j(g,\tau) \begin{pmatrix} g\tau \\ 1 \end{pmatrix}.$$

We now get

$$j(gh,\tau) \begin{pmatrix} gh\tau \\ 1 \end{pmatrix} = gh \begin{pmatrix} \tau 1 \end{pmatrix} = g \left( j(h,\tau) \begin{pmatrix} h\tau \\ 1 \end{pmatrix} \right) = j(h,\tau) j(g,h\tau) \begin{pmatrix} gh\tau \\ 1 \end{pmatrix},$$

which finishes the computation and proof.

**Formulae.** For  $g \in GL_2(\mathbb{R})^+, \tau \in \mathfrak{H}$ , we have

$$\operatorname{Im}(g\tau) = \det(g) \frac{\operatorname{Im}(\tau)}{|j(g,\tau)|^2} \text{ and } j(g,\tau) \begin{pmatrix} g\tau \\ 1 \end{pmatrix} = g \begin{pmatrix} \tau \\ 1 \end{pmatrix}.$$

**Definition 1.3.** Let  $k \in \mathbb{Z}$  and  $\gamma \leq \Gamma(1)$  of finite index<sup>1</sup>. A weakly modular function of weight k and level  $\Gamma$  is a meromorphic function  $f : \mathfrak{H} \to \mathbb{C}$  which is invariant under the weight k action of  $\Gamma$ , i.e. such that

$$\forall \tau \in \mathfrak{H}, \forall \gamma \in \Gamma, f|_k(\gamma) = f.$$

We will define modular forms next time: they are weakly modular functions which are holomorphic both in  $\mathfrak{H}$  and at  $\infty$ .

It is a fact that modular forms of fixed weight and level live in finitedimensional  $\mathbb{C}$ -vector spaces called  $M_k(\Gamma)$ . These form the main objects of study in this course.

**Motivation.** Why study modular forms?

(1) They are related to the theory of elliptic functions. Let  $E/\mathbb{C}$  be an elliptic curve and  $\omega$  a holomorphic non–zero 1–form. Then there exists a unique lattice<sup>2</sup>  $\Lambda \in \mathbb{C}$  and isomorphism  $\phi : \mathbb{C}/\Lambda \to E$  such that  $\phi^*(\omega) = dz$ . Then

<sup>&</sup>lt;sup>1</sup>In other words,  $\gamma$  is a (finite index) subgroup of  $\Gamma(1)$ .

<sup>&</sup>lt;sup>2</sup>i.e. a discrete cocompact subgroup, or an abelian subgroup which is freely generated by two elements that are linearly independent over  $\mathbb{R}$ .

E is isomorphic to the elliptic curve  $y^2 = 4x^3 - 60G_4(\Lambda)x - 140G_6(\Lambda)$  where if  $k \in \mathbb{Z}$ , then  $G_k(\Lambda) = \sum_{\lambda \in \Lambda - \{0\}} \lambda^{-k}$ . This converges absolutely for k > 2. If  $\tau \in \mathfrak{H}$ , then  $\Lambda \tau = \mathbb{Z}\tau \oplus \mathbb{Z} \subset \mathbb{C}$  is a lattice and  $G_k(\tau) = G_k(\Lambda_\tau)$ . This is a modular form of weight k and level  $\Gamma(1)$ , called an Eisenstein series.

 $\mathfrak{H}/SL_2(\mathbb{Z})$  can be identified with the set of (isomorphism classes of) elliptic curves over  $\mathbb{C}$ .

- (2) Modular forms f have Fourier expansions  $\sum_{n\in\mathbb{Z}} a_n g^n$ ,  $a_n \in \mathbb{C}$  and they often serve as a generating functions for arithmetically interesting sequences  $a_n$ .
  - For example, take  $\theta(\tau) = \sum_{n \in \mathbb{Z}} e^{\pi i n^2 \tau}$ . If  $k \in 2\mathbb{N}$ , then  $\theta^k$  is a modular form with q-expansion  $\theta^k = \sum_{n \in \mathbb{Z}} r_k(n) e^{\pi i n \tau}$ , where  $r_k(n)$  is the number of ways of writing n as a sum of k squares, i.e.  $r_k(n) = |\{x \in \mathbb{Z}^k \mid \sum_{i=1}^k x_i^2 = n\}|$ . By expressing  $\theta^k$  in terms of other modular forms, we can prove formulae such as  $r_4(n) = 8 \sum_{d|n.4\nmid d} d$ .
- (3) The Riemann zeta function  $\zeta(s)$  is an important object of study. Its pleasant features include:
  - The Euler product  $\zeta(s) = \prod_{p} (1 p^{-s})^{-1}$ .
  - It has a meromorphic continuation to  $\mathbb{C}$  and has a functional equation relating  $\zeta(s)$  and  $\zeta(1-s)$ .

A Dirichlet series  $\sum_{n\geq 1} a_n n^{-s}$  which has similar properties (Euler product, meromorphic extension, some nice function equation) is called an L-function. Modular forms can be used to construct interesting examples of L-functions. In practice, we take  $M_k(\Gamma)$  and decompose it under Hecke operators to get Hecke eigenforms, the nicest possible modular forms, which have the above properties.

(4) The Langlands program predicts a relation between modular forms and objects in arithmetic geometry. A special case of this is the modularity conjecture, which says that there is a bijective correspondence between elliptic curves  $E/\mathbb{C}$  up to isogeny and the set of Hecke eigenforms of weight 2. This implies Fermat's last theorem. Note that this is formulated in the language of Hecke operators and L-functions.

**Homework.** There is a handout on Moodle called "Reminder on Complex Analysis". Have a look at it before the next lecture.

#### Modular Forms on $\Gamma(1)$ $\mathbf{2}$

**Reminder.** A meromorphic function in an open subset  $U \subset \mathbb{C}$  is a closed subset  $A \subset U$  and a holomorphic function  $f: U \setminus A \to \mathbb{C}$  such that  $\forall a \in A$ ,  $\exists \delta > 0$  such that  $D^*(a,\delta) \subset U \setminus A$  and  $\exists n \geq 0$  such that  $(z-a)^n f(z)$  extends to a holomorphic function in  $D(a, \delta)$ .

09 Oct 2022,

Lecture 2

f then has a Laurent expansion  $\sum_{m\in\mathbb{Z}} a_m(z-a)^m$  valid on  $D^*(a,\delta)$ .

**Lemma 2.1.** Let f be a weakly modular function of weight k and level  $\Gamma(1)$ . Then there exists a meromorphic function f in  $D^*(0,1)$  such that  $f(\tau) =$  $\tilde{f}(e^{2\pi i \tau}).$ 

*Proof.* f is meromorphic in  $\mathfrak{H}$  by assumption. Take  $\gamma = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \Gamma(1)$ . Then  $f|_h[\gamma](\tau) = f(\gamma\tau) = f(\tau)$ , as f is invariant under the weight k action of  $\gamma$ . But also  $f(\gamma \tau) = f(\tau + 1)$ , so f is periodic.

Now map a strip of  $\mathfrak{H}$  of width 1 to  $D^*(0,1)$  by  $\tau \mapsto e^{2\pi i \tau}$ . Existence of  $\tilde{f}$ : Let  $a \in D^*(0,1)$  and  $\delta > 0$  be such that  $D(\alpha,\delta) \subset D^*(0,1)$ . Define  $\tilde{f}$  on  $D(a,\delta)$  by  $\tilde{f}(q)=f(\frac{1}{2\pi i}\log q)$ , for any branch of log defined in  $D(a,\delta)$ . This is meromorphic and independent of the choice of the branch of  $\log$ , as f is periodic with period 1. This defines  $\tilde{f}$  in  $D^*(0,1)$ .

 $\tilde{f}$  is unique since  $\tau \mapsto e^{2\pi i \tau}$  is surjective.

If  $\tilde{f}$  extends to a meromorphic function<sup>3</sup> in D(0,1), then  $\exists \delta > 0$  such that  $\tilde{f}$  has a Laurent expansion  $\tilde{f}(q) = \sum_{n \in \mathbb{Z}} a_n q^n$  valid in  $D^*(0, \delta)$ .

In the region  $\{\tau \in \mathfrak{H} \mid \operatorname{Im}(\tau) > \frac{1}{2\pi} \log \delta\}$ , we have

$$f(\tau) = \sum_{n \in \mathbb{Z}} a_n q^n,$$

where  $q = e^{2\pi i \tau}$ . This is called the q-expansion of the weakly modular function f.

**Definition 2.1.** Let f be a weakly modular function of weight k and level  $\Gamma(1)$ . We say that f is **meromorphic at**  $\infty$  if  $\tilde{f}$  extends to a meromorphic function in D(0,1).

We say f is holomorphic at  $\infty$  if  $\tilde{f}$  is meromorphic at  $\infty$  and has a removable singularity at q=0. In this case, we define  $f(\infty)=\tilde{f}(0)=$  $\lim_{\mathrm{Im}(\tau)\to\infty} f(\tau)$ 

We say f vanishes at  $\infty$  if f is holomorphic at  $\infty$  and  $f(\infty) = 0$ .

<sup>&</sup>lt;sup>3</sup>This might not be the case if the set of poles has a limit inside the disk.

**Definition 2.2.** A modular function (of weight k and level  $\Gamma(1)$ ) is a weakly modular function (of weight k and level  $\Gamma(1)$ ) which is meromorphic at  $\infty$ .

A **modular form** is a weakly modular function which is holomorphic in  $\mathfrak{H}$  and holomorphic at  $\infty$ .

A cuspidal modular form is a modular form that vanishes at  $\infty$ .

**Remark.** We let  $M_k(\Gamma(1))$  denote the set of modular forms of weight k and level  $\Gamma(1)$ . We write  $S_k(\Gamma(1))$  for the set of cuspidal modular forms of weight k, level  $\Gamma(1)$ . Note  $S_k(\Gamma(1)) \subset M_k(\Gamma(1))$ . These are  $\mathbb{C}$ -vector spaces. If k is odd, then these both only contain the zero function, since taking  $\gamma = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \in \Gamma(1)$  gives  $f|_k[\gamma](\tau) = f(\tau)(-1)^k = f(\tau)$ .

We now consider even weights only. If  $k \in \mathbb{Z}$  is even, let

$$G_k(\tau) = \sum_{\lambda \in \Lambda_{\tau} \setminus 0} \lambda^{-k} = \sum_{(m,n) \in \mathbb{Z}^2 \setminus 0} (m\tau + n)^{-k},$$

where  $\Lambda_{\tau} = \mathbb{Z}\tau \oplus \mathbb{Z}$  for any  $\tau \in \mathfrak{H}$ .

If  $\gamma \in \Gamma(1)$ , then formally we have

$$G_k|_k[\gamma](\tau) = G_k(\gamma\tau)j(\gamma,\tau)^{-k} = \sum_{\lambda \in \Lambda_{\gamma\tau} \setminus 0} \lambda^{-k}j(\gamma,\tau)^{-k},$$

but  $\Lambda_{\gamma\tau} = \mathbb{Z} \frac{a\tau+b}{c\tau+d} \oplus \mathbb{Z} = (c\tau+d)^{-1} (\mathbb{Z}(a\tau+b) \oplus \mathbb{Z}(c\tau+d)) = (c\tau+d)^{-1} \Lambda_{\tau}$ . Hence

$$G_k|_k[g](\tau) = \sum_{\lambda \in (c\tau+d)^{-1}\Lambda_\tau \setminus 0} \lambda^{-k} (c\tau+d)^{-k}$$
$$= \sum_{\lambda \in (c\tau+d)^{-1}\Lambda_\tau \setminus 0} ((c\tau+d)^{-1}\lambda)^{-k} (c\tau+d)^{-k} = G_k(\tau).$$

This is justified only when the series defining  $G_k(\tau)$  converges absolutely. Hence:

**Proposition 2.2.** Let k > 2 be an even integer. Then  $G_k(\tau)$  converges absolutely and defines a modular form of weight k and level  $\Gamma(1)$  with  $G_k(\infty) = 2\zeta(k)$ .  $G_k$  is the **weight** k **Eisenstein series**.

We will later see that  $M_2(\Gamma(1)) = 0$ .

*Proof.* We want to show absolute and locally uniform convergence in  $\mathfrak{H}$ . This will show that  $G_k$  is holomorphic by complex analysis. Let  $A \geq 2$  and define

 $\Omega_A = \{ \tau \in \mathfrak{H} \mid \operatorname{Im}(\tau) \geq \frac{1}{A}, \operatorname{Re}(\tau) \in [-A, A] \}.$  We show uniform convergence in  $\Omega_A$ . If  $\tau \in \Omega_A, x \in \mathbb{R}$ , then  $|\tau + x| \ge \begin{cases} \frac{1}{A} & |x| \le 2A \\ \frac{|x|}{2} & |x| > 2A. \end{cases}$  Hence

$$|\tau + x| \ge \sup\left(\frac{1}{A}, \frac{|x|}{2A^2}\right) \ge \sup\left(\frac{1}{2A^2}, \frac{|x|}{2A^2}\right) = \frac{1}{2A^2}\sup(1, |x|).$$

If  $(m,n) \in \mathbb{Z}^2$ ,  $m \neq 0$ , then

$$|m\tau + n| = |m||\tau + \frac{n}{m}| \ge \frac{1}{2A^2} \sup\left(1, \left|\frac{n}{m}\right|\right) \cdot |m| = \frac{1}{2A^2} \sup\left(|m|, |n|\right).$$

This is also valid when m=0 by inspection. If  $\tau \in \Omega_A$ , then

$$\sum_{(m,n)\in\mathbb{Z}^2\backslash 0} |m\tau + n|^{-k}$$

$$\leq \left(\frac{1}{2n^2}\right)^{-k} \sum_{(m,n)\in\mathbb{Z}^2\backslash 0} \sup(|m|,|n|)^{-k}$$

$$= (2A^2)^k \sum_{d\in\mathbb{N}} d^{-k} \cdot \left| \{(m,n)\in\mathbb{Z}^2 \mid \sup(|m|,|n|) = d \} \right|$$

$$= (2A^2)^k \sum_{d\in\mathbb{N}} d^{-k}8d = 8(2A^2)^k \sum_{d\in\mathbb{N}} d^{1-k}$$

$$< \infty$$

whenever k-1>1, i.e. k>2. This shows absolute convergence, and uniform convergence in  $\Omega_A$  by the Weierstrass M-test<sup>4</sup> Hence  $G_k$  is holomorphic in  $\mathfrak{H}$ and invariant under the weight k action of  $\Gamma(1)$ . It remains to show that  $G_k$  is holomorphic at  $\infty$  with  $G_k(\infty) = 2\zeta(k)$ . For this, it suffices to check that

$$\lim_{\mathrm{Im}(\tau)\to\infty} G_k(\tau) = 2\zeta(k).$$

This follows from uniform convergence in  $\Omega_A$ : we get

$$\lim_{\mathrm{Im}(\tau)\to\infty} G_k(\tau) = \sum_{(m,n)\in\mathbb{Z}^2\setminus 0} \lim_{\mathrm{Im}(\tau)\to\infty} (m\tau+n)^{-k} = \sum_{n\in\mathbb{Z}\setminus 0} n^{-k} = 2\sum_{n\geq 1} n^{-k} = 2\zeta(k).$$

<sup>&</sup>lt;sup>4</sup>If we have a sequence of functions  $f_n: \Omega \to \mathbb{C}, M_n > 0, |f_n(x)| < M_n \text{ and } \sum M_n < \infty,$ then  $\sum f_n$  converges uniformly
